Server Crash Course

Condensed information of servers into 7 slides

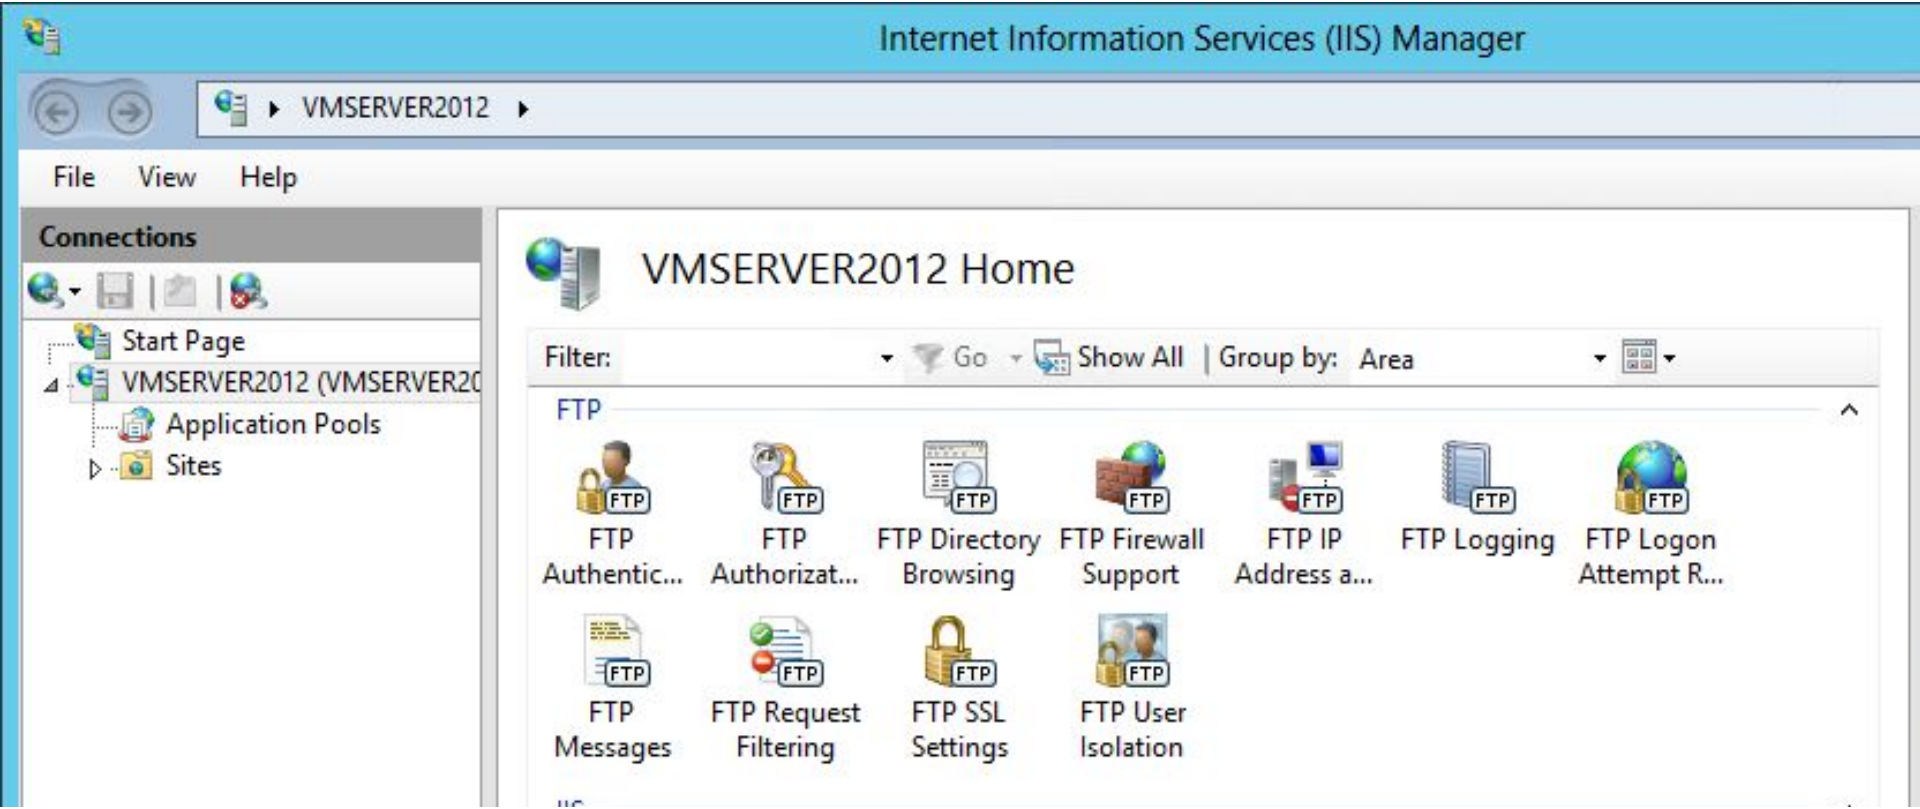

*not all details included

SMB (fsmgmt.msc) - file sharing over network

- Use common sense
  - Make sure the share is authorized
  - Set correct permissions
    - If it's to be public, do Everyone Read-only
    - If it's to be private, set the appropriate rights to the users/groups involved with the share
- Uninstall the insecure SMB1 (or update to patch if it is necessary)

FTP - SMB but across different networks and OS

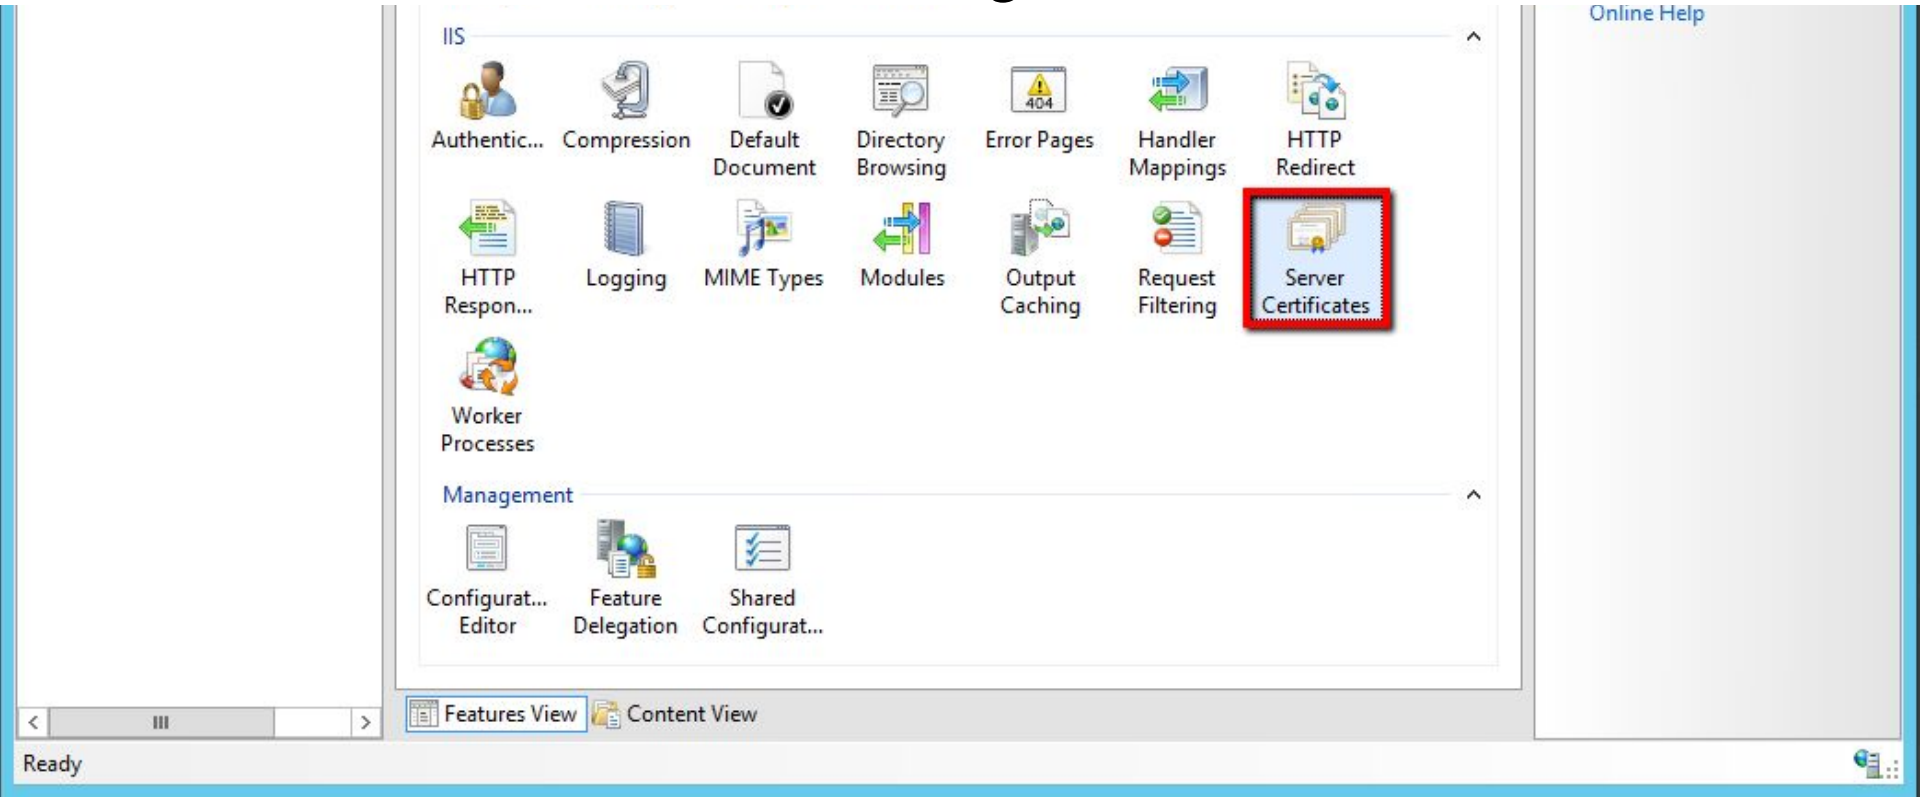

Win+R “inetmgr” or use Windows Search. You have authentication, directory browsing, logging, messages, and more. Turn off directory browsing, turn on logging, etc.

Filezilla FTP Server - a program, not a role

- Run the admin panel, connect with default settings
  - Usually “localhost” and “14147” with no password
- Edit > Settings
  - Security settings - choose highest protection [Require...]
  - Turn on autoban
  - Turn on logging
  - Enable FTP over TLS
- Edit > Users, and Edit > Groups
  - Manage users (add/remove if needed), set passwords, set proper directory permissions according to POLP theory

_ **Web Server IIS** - web hosting

IIS options, also in inetmgr (IIS Manager). Similar to Microsoft FTP configuration - turn off directory browsing, turn on logging, etc

The websites' root folder is located in C:\inetpub\wwwroot

Wordpress - another more simple website hosting platform

- Accessing the wordpress site locally depends on how it is set up
  - Generally “localhost/wordpress” in web browser
- Admin panel is generally “localhost/wordpress/wp-admin”
  - Use supplied credentials in README to log in
- Admin dashboard (once you log in)
  - think of Wordpress as an OS with settings you need to configure
    - ex: do update, users, media, prevent multiple login attempts
  - also think of Wordpress as IIS
    - ex: disable directory browse
  - also disable file editing via wp-config.php (found under site root folder)
  - several security settings are done via plugins
    - likelihood of scoring is slim
